Topic 5 - n8n Workflow Evidence Report

Loop Processing, Pagination & Rate-Limited Batching | 21 October 2026

Final execution status: COMPLETED

Metric	Result
Total users processed	23
Classified SENT	22
Classified FAILED	1
Batch size	5
Total batches	5
HTTP page fetches	4
Final status	COMPLETED

Objective

Demonstrate paginated retrieval of 23 mock users, processing in controlled batches of five, simulated email requests, failure classification, and a consolidated execution summary.

Workflow architecture

Manual Trigger -> Set Config -> Code_InitPaging -> HTTP_FetchPage -> IF_HasMorePages -> Code_AccumulatePage (pagination loop) -> Code_PrepareDataset -> Loop_Over_Items -> HTTP_SendSimulatedEmail -> Code_ClassifyResult -> Wait_RateLimitPause (batch loop) -> Code_BuildExecutionSummary.

Mock API architecture

Webhook (GET /mock/api/users) -> Generate_23_Users -> Respond to Webhook. The mock endpoint supports page and limit query parameters and includes an intentionally invalid email for User 13.

Execution interpretation

The main workflow screenshot shows green checks throughout, four HTTP page-fetch executions, 23 users routed to batching, five simulated-email node executions, and the summary node completing. The mock API screenshot shows a successful published webhook execution with all three nodes green.

Failure handling

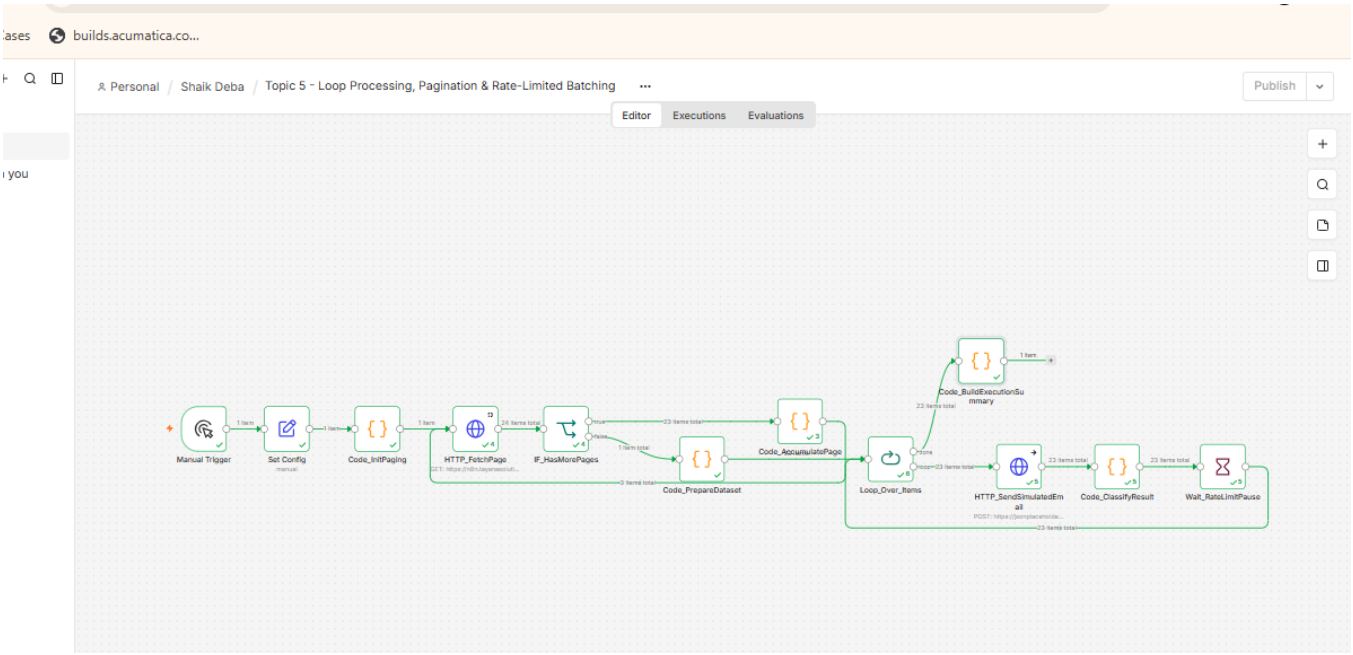

The invalid email bad-email-format for User 13 was classified as FAILED by workflow logic. JSONPlaceholder POST is a simulated endpoint; this evidence does not demonstrate actual email delivery or an HTTP rejection of the invalid address.

Evidence limitations

The two attached screenshots verify workflow topology and successful executions. The precise 22 SENT / 1 FAILED / 5 batches totals are taken from the final summary output shared earlier in this conversation, not displayed in the two attached screenshots. The configured two-second wait and actual timing between batches are not independently proven

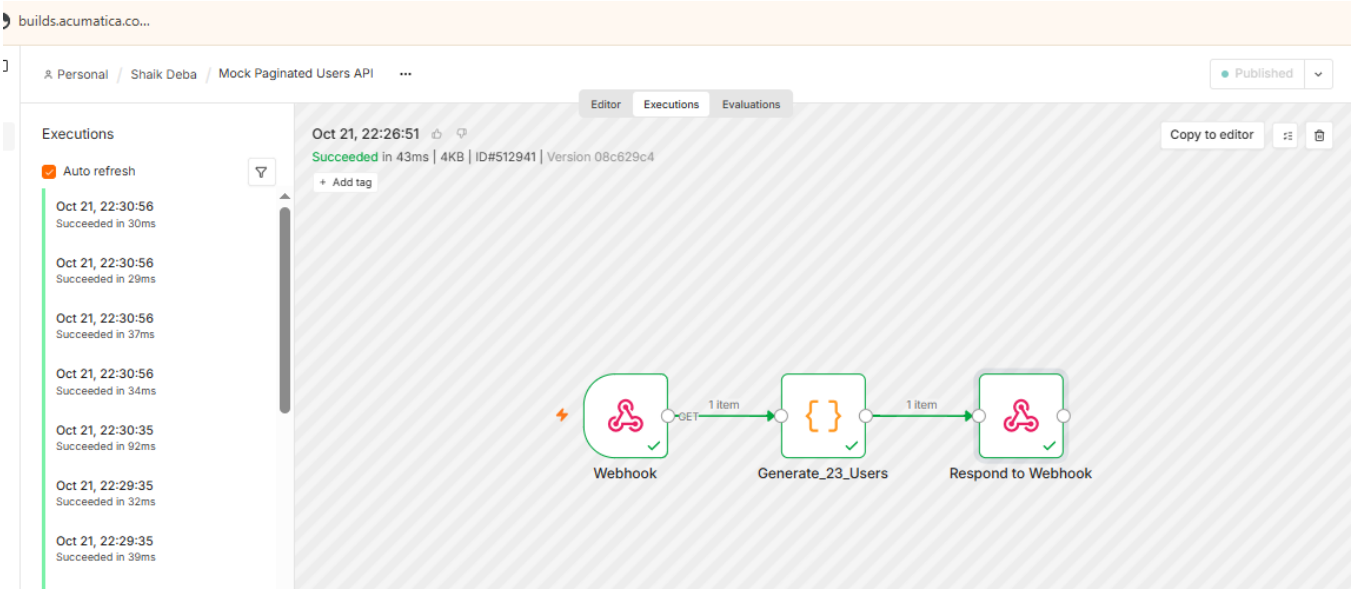

by these screenshots.

Evidence 1 - Main workflow execution

Complete Topic 5 pipeline. Green indicators show successful execution; 23 records reach batching and the summary node completes.

Evidence 2 - Mock API execution

Published mock API with Webhook, Generate_23_Users, and Respond to Webhook nodes all showing success.

Test checklist

• Pagination: 23 users across four fetches; stopped at empty page.

• Batching: five batches at a configured size of five.

• Failure tolerance: 22 SENT, 1 FAILED in final summary.

• Rate-limit: Wait node executed; exact intervals not independently verified.

• Summary: COMPLETED status recorded.

Conclusion

The final reported run met the core processing scenario. Actual email delivery was not tested; simulated POST results and local classification were used. Exported workflow JSON and execution logs would provide additional audit evidence.
